Oceanographic Unit
Washington, D.C.**

April 1978

ABSTRACT

During 1975 five oceanographic cruises were made by the U.S. Coast Guard to the Grand Banks region. During April (IIP-1-75) a large anti-cyclonic eddy was observed between the Labrador Current and the North Atlantic Current. The eddy appeared to move southward and rejoin the North Atlantic Current. Six occupations of standard section A3, spaced throughout the year, revealed a relatively smooth pattern of variation for the Labrador Current with maximum southward transport and minimum water temperature in April changing to minimum transport and maximum temperature in November. However, repeated occupation of standard section A1 over a 54 hour period indicated that large variations in the Labrador Current transport do occur over short time scales.

OCEANOGRAPHY OF THE GRAND BANKS REGION OF NEWFOUNDLAND

1975

DAVID G. MOUNTAIN

INTRODUCTION

During 1975 five oceanographic cruises were made by the U.S. Coast Guard to the Grand Banks region (fig. 1). The majority of data presented were obtained during two cruises by the International Ice Patrol (April and May-June 1975) aboard the USCGC EVERGREEN (WAGO 295). These observations were made in support of Commander, International Ice Patrol to aid in the prediction of the drift of icebergs into the North Atlantic. Three additional cruises were conducted in connection with the Coast Guard Standard Section Program. Standard Sections A2, A3, and A4 were occupied in February and August by the USCGC CHASE and in November by the USCGC HAMILTON. In each case sections A3 and A4 were extended seaward of the limits shown in figure 1. A summary of the observations made on each cruise is given in Table 1.

INTERNATIONAL ICE PATROL CRUISES

April Cruise: The first Ice Patrol cruise included two oceanographic surveys. The first survey (4-15 April) consisted of sections A3C, A3B, A3A, A3, and A2B (fig. 1), while the second (21-25 April) reoccupied sections A3, A3A, and A3B. A total of 90 oceanographic casts were made using an salinity, temperature, depth environmental profiling system (STD) to yield IIP stations 11690-11779.

On April 12, during the first survey, a subsurface mooring with two current meters, deployed in June 1974, was recovered. The mooring was located at 44°41.7'N, 48°55.0'W in 587 fm (1086 m) of water. Discussion of the data from these current meters is contained in Weir (1977). Between the STD surveys a subsurface moored

current meter array was deployed on 19 April 1975 in 165 fm (305 m) of water at 45°44.0'N, 48°06.7'W. The mooring, which was retrieved in June 1975 on the second IIP cruise, is described in section Current Meter Measurements. Following the deployment, a series of casts were made around the mooring site using a conductivity, temperature, depth environmental profiling system (CTD), to allow comparison of the directly measured currents and the calculated geostrophic currents.

During transit to and from the Grand Banks region an expendable bathythermograph (XBT) survey was conducted for the National Marine Fisheries Service. When the CGC EVERGREEN was between 65°W and 70°W, an XBT was taken every hour. Forty-five such XBT measurements were made on the April IIP cruise.

The scientific party for the first IIP cruise was

Mr. R. M. Hayes—Field Party Chief

MST3 D. Startt
MST3 S. Pepovitch
ET3 L. Haney

May-June cruise: The second IIP cruise consisted of three segments. The first began with an intensive STD survey in a 66x60 mile grid, the southwest corner of which was located at 43°50'N, 49°15'W. The grid, which contained five east-west sections of eight stations each, was occupied between 26-28 May. The survey was

conducted to provide input to a real-time numerical model of the Labrador Current (Kollmeyer, 1975). Following occupation of sections A2, A2B, and A2C, the intensive survey was repeated between 3-6 June to allow for the verification of the numerical model.

The second segment of the cruise involved a dual ship study of iceberg drift. While the USCGC SHERMAN (WHEC 720) stood by a medium size iceberg as it drifted, the CGC EVERGREEN made four sections, totaling 43 STD stations, perpendicular to the path of the iceberg's drift. The final section occupied coincided with IIP standard section A1A. The iceberg was followed for a period of four days (15-19 June).

During the final segment of the second IIP cruise the current meter array deployed on 19 April 1975 was recovered on 27 June 1975. On 28 June Standard Monitoring Section A1 was occupied beginning at the shallow (West) end. The trackline was then retraced dropping an XBT probe approximately every mile (57 XBT casts) after which section A1 was repeated on 1 July.

Hourly XBT measurements were again made for the National Marine Fisheries Service under the same guidelines applied to the first cruise. These data are presented in Cook (1975).

Standard Section Occupations—A2, A3, A4

The USCGC CHASE (WHEC 718) occupied standard sections A2, A3, and A4 between 2-17 February. The measurements were made using Nansen bottles with deep sea reversing thermometers. The CGC CHASE reoccupied these same sections between 30 August-4 September using

an STD profiling system. A third occupation of standard sections A2, A3, and A4 was accomplished by the USCGC HAMILTON (WHEC 715) from 15 to 23 November using Nansen bottles with reversing thermometers.

INSTRUMENTS AND METHODS

IIP Cruises: The STD measurements were made with a Plessey 9040 STD profiling system. The three analog FM signals from the STD deck unit (depth, temperature, and salinity) were converted to binary decimal frequency values (integer cycles per second) by General Radio Model 1192 frequency counters and digitized by a Soncraft Co. Digital Data Logger (DDL). The digitized frequency values were then recorded on 1/2 inch computer compatible seven track magnetic tape by a Kennedy 1600R incremental tape recorder. The observations of depth, temperature, and salinity were made simultaneously at a one second rate and recorded serially on the magnetic tape.

The recorded data was processed through a series of three programs on a CDC-3300 computer to yield the final data values listed in this report. The original data tape was input to program NEWDL which converted the frequency data to geophysical units. The converted data was both printed out and written on a separate magnetic tape. From the printout the first and last good data levels were determined, as were values for comparison with quality control samples to derive temperature and salinity correction values (see below). The NEWDL output tape was used as input to program AVMUL. This program deleted all observations in which the depth decreased from the previous observation, applied the quality control correction values, calculated sigma-t for each observation, averaged temperature and salinity values for observations at the same depth, and from those determined an average sigma-t at each depth. The output of AVMUL was both a printout and a magnetic tape. The printout was reviewed to identify bad data points which resulted in unrealistic instabilities in the water column, primarily due to the slow thermometer response time in regions of sharp thermal gradient. The stability criteria used is that established by the National Oceanographic Data Center. The AVMUL output tape was input to program FINPT which deleted selected levels, reaveraged the values at common

depths, and determined temperature, salinity, and sigma-t values at standard levels and significant points in a manner described by Rosebrook (1974). The output of FINPT represented the final form of the data as presented in this report.

For the stations occupied using a Plessey 9040 CTD profiling system the same acquisition and processing scheme was used with one modification. In program NEWDL the conductivity value was converted to a salinity value using equations developed by Brown as presented by Jaeger (1973).

The data in its final form was processed through program XPORT. This program calculated dynamic height values relative to 1000 dbar level and from those, geostrophic currents between stations on a section. Dynamic height values for stations less than 1000 m were calculated relative to a 1000 dbar reference level using a method described by Kollmeyer et. al. (1967), based on the technique developed by Helland-Hansen (1934). The method treats the sediment under the shallow stations as motionless water. The technique is subjective and introduces some uncertainty in the calculation of current and transport values, particularly for the Labrador Current which usually straddles the 1000 m isobath.

For quality control a Nansen bottle with two protected and two unprotected deep sea reversing thermometers was placed approximately three meters above the STD instrument on each cast and was tripped at the deepest depth of the cast, after allowing sufficient soak time. Surface temperature and water samples were obtained at alternate stations by bucket. Salinity values were determined by a Plessey 6220 salinometer. The difference between the Nansen bottle and the recorded STD values yielded temperature and salinity corrections. The correction values for the surface and 1000 m were plotted against time for each instrument to identify periods during which the instrument offset was fairly constant. Within each period an average temperature and salinity correction was determined. The correction values at mid-depth were used to check the shear between the surface and the 1000 m values. The surface temperature corrections were highly scattered; therefore the 1000 m values were used as a correction constant with depth and ranged from $+0.13^{\circ}\text{C}$ to -0.05°C . The salinity cor-

rection values varied from $+0.053\text{‰}$ to -0.053‰ at the surface and 0.079‰ to -0.017‰ at 1000 m.

Standard Monitoring Section Occupations: The standard section cruises employed both an STD system and standard Nansen bottle casts at different times. The Nansen casts were processed in accordance with CG 410. The STD data were recorded in analog form on a Leeds and Northrup ink pen recorder. The temperature and salinity values were read from the analog trace at standard levels and significant points. Temperature and salinity correction values were derived from quality control samples obtained by a Nansen bottle attached above the STD instrument and tripped at the deepest depth of the cast.

THE DATA

The STD data discussed above are presented at the end of this report. The temperature and salinity distributions along each section of stations occupied are presented in chronological order in figs. 15 to 49.

CURRENT METER MEASUREMENTS

A current meter mooring was deployed during the first IIP cruise on 19 April at $45^{\circ}44.0'\text{N}$, $48^{\circ}06.1'\text{W}$ in 305 m of water. The mooring was successfully recovered during the second IIP cruise on 26 June. The deployment was accomplished from the buoy deck of the CGC EVERGREEN by an anchor-last technique.

The mooring (fig. 2) included one AMF Corporation vectoring averaging current meter (model number 610B, serial number 282), an AMF Corporation acoustic release (model 284, serial number 174), and an inclinometer, a depth gage, and a tensiometer manufactured by General Oceanics Inc. Flotation was provided by twelve 16" corning glass balls in plastic hard hats. The mooring was designed through use of a computer program adapted from one developed by Berteau and Chhabra (1973). The results from the various instruments were to be compared against the mooring configuration predicted by the computer program.

All of the instruments functioned properly with the exception of the current meter, which malfunctioned and yielded no reliable data. Examination of the meter by the manufacturer indicated that the current meter malfunctioned

at cold temperatures comparable to the water temperature in the area of the mooring site ($<4^{\circ}\text{C}$).

Due to the current meter failure, the other data obtained in connection with the mooring are not presented. The mooring line tension and inclination, and current meter depth, as recorded by the additional instrumentation, were compatible with the computer prediction for anticipated current speeds.

DYNAMIC TOPOGRAPHY

The circulation regime in the Grand Banks area is usually characterized by a cold, narrow Labrador Current flowing southward along the steep continental slope and by a warm broad North Atlantic Current flowing northeastward further off shore to the east. The corresponding dynamic topography (fig. 3) derived from monthly mean values (Scobie, 1976) is characterized by closely spaced contours indicating the two currents and widely spaced contours forming a broad dynamic trough between them.

The dynamic topography for the first IIP survey (8 to 20 April, fig. 4) indicates the Labrador Current flowing southward over the steep slope along the eastern edge of the Grand Banks, generally between the 500 and 2000 m isobaths. The maximum geostrophic velocities in the current ranged from 28–65 cm/sec at the different sections. Along the eastern edge of the survey area the North Atlantic Current flowed northeastward with speeds of 45–75 cm/sec. Between the two currents was a large (130 km diameter) anticyclonic eddy, centered at $44^{\circ}30'\text{N}$, $48^{\circ}00'\text{W}$. The presence of the eddy was likely responsible for a portion of the Labrador Current being diverted to the east along the northern side of the eddy. The warm core eddy probably was shed from the North Atlantic Current in a manner similar to that observed on the north side of the Gulf Stream (Saunders, 1971). The temperatures and geostrophic current across section A3A (figs. 20a and c), which passed through the eddy, indicate that the eddy structure extended at least to 1000 m depth. If a significant secondary circulation was driven by viscous forces within the eddy, the secondary flow at the surface would be radially outwards. The implication would be that icebergs would tend to remain on the periphery of the eddy and not be drawn to the eddy interior.

The Labrador Current during the second survey (21–25 May), as revealed by the dynamic topography (fig. 5), changed little from the first survey. The anticyclonic eddy appeared to have moved southeastward and rejoined the North Atlantic Current, although the limited nature of the survey precludes full delineation of the feature. This southeastward movement of the eddy approximately paralleled to local bottom topography, which would be expected for bathymetrically controlled eddy movement (Warren, 1967). Estimation of the speed of the movement is difficult since the eddy could have intersected the North Atlantic Current at any time between the surveys. The displacement of the eddy/meander center over the time between the surveys yields a speed of only 1 cm/sec.

The dynamic topography for both intensive surveys (figs. 6 and 8) indicate the Labrador Current flowed south over the steep continental slope, as is normally observed. Both also indicate that the North Atlantic Current entered the area from the southeast, turned clockwise, and exited to the northeast. The major change which occurred in the 8–10 days between the observations was that the dynamic trough between the Labrador Current and the North Atlantic Current deepened (970.92 dyn m to 970.88 dyn m) and extended southward. The standard sections occupied between the intensive surveys (fig. 7) suggest that the curving of the North Atlantic Current in figs. 6 and 8 was part of an eddy/meander feature similar to that observed in the April surveys.

The standard sections occupied in February, August, and November do not allow contouring of the dynamic topography due to the large spatial separation between the sections. The dynamic height values for each survey are plotted in figs. 9, 10, and 11, with the direction of the surface geostrophic current indicated by an arrowhead.

LABRADOR CURRENT TRANSPORT

The spatial and temporal variations of the transport of water by the Labrador Current may be investigated by comparing the calculated geostrophic volume transports at the various sections occupied. Due to inherent inaccuracies in the method of calculation, the variations are likely significant only in their general trend and not in their exact magnitude. The minimum tempera-

ture observed and three measures of the Labrador Current transport (total, $<2^{\circ}\text{C}$, $<0^{\circ}\text{C}$) are given in Table II for each of the sections occupied.

Considering sections occupied nearly simultaneously (within the same survey) a general decrease in transport and increase in minimum temperature is noticed in going from north to south. These spatial changes are expected since, as the water in the current moves southward, it continuously mixes with the warmer water offshore in the North Atlantic Current to form a large pool of mixed water (Hawley and Soule, 1940) in the dynamic trough between the two currents. The decrease in southward transport suggests that no major contribution is made to the Labrador Current by water from the Grand Banks region to the west. Apparent influxes of water from the Grand Banks indicated in the dynamic topography (e.g., fig. 6) are likely due to a lack of synopticity in the data, as well as being an artifact of the extrapolation technique used in shallow water.

The temporal change in the Labrador Current transport is seen by comparing the values at section A3, which was occupied six times during the year (fig. 13). All three measures of the volume transport increase to a maximum in April and decrease during the rest of the year. The maximum total southward transport in April is

approximately twice the minimum value in November. The minimum temperature also exhibits extremes in April and November, with the April value being more than two degrees colder than observed in November.

A second view of the temporal change in the Labrador Current is obtained from the three occupations of section A1 (two by STD, one by XBT) within a 58 hour period. The geostrophic currents indicate an increase in transport, particularly of cold ($<0^{\circ}\text{C}$) water, over that time. The temperature cross sections (figs. 14, 39A, and 40A) show the area of cold water increasing with time. The -1°C envelope extended eastward more than 20 km over the outer shelf during the period. The XBT section temperature distribution, while more patchy, is intermediate between the STD observations, suggesting that a progressive change was occurring in the Labrador Current properties. The implication is that, while a fairly smooth yearly pattern may be evident in fig. 13, significant changes in water properties and volume transport do occur on relatively short time scales. Similar results have been obtained by repeated occupation of section A3 closely spaced in time (Wolford, 1966).

APPENDIX A

OCEANOGRAPHIC DATA

Cruises Listed	
I. USCGC CHASE, February, 1977 -----	58
II. USCGC EVERGREEN, April and May-June, 1977 -----	83
III. USCGC CHASE, August-September, 1977 -----	304
IV. USCGC HAMILTON, November, 1977 -----	336

Codes Utilized

A complete description of the codes utilized in the tabulation of oceanographic station data can be found in National Oceanographic Data Center publication M-2, **Processing Physical and Chemical Data from Oceanographic Stations**. (Rev. August 1964, supplement issued May 1966.)

To facilitate use of the oceanographic station data listing, entry headings which are not self-explanatory are described below.

REFID	NODC reference identity number.
CONSEC	Consecutive station number.
BOTDP (B)	Uncorrected sounding depth in meters.
SHIP (B)	NODC assigned platform identity code.
DATA USE	Entry 1 identifies DNP data.
AREA	NODC ocean area code.
CLOUD T/A (B)	Cloud type according to WMO code 0500 and cloud amount according to WMO code 2700
Wave observations	
DIR	Direction from which dominant waves are coming in tens of degrees according to WMO code 0885.
HGT	Height of dominant waves according to WMO code 1555.
PER	Period of dominant waves according to WMO code 3155.
SEA (B)	Sea state according to WMO code 3700.
CL/TR (B)	Water color according to fore-I-Ue code. Transparency in meters as determined by Secchi disc.
WIND DIR (B)	Direction from which wind is blowing in tens of degrees according to WMO code 0877
WIND SPD (B)	Wind speed in knots.
WIND FOR (B)	Wind force in beaufort code.
WEATHER (B)	Weather code—If preceded by letter X is according to WMO code 4501. A numeric two digit entry indicates weather according to WMO code 4677.
INST	Instrument used for observation—"Nansen Cast" indicates station consists of Nansen cast data—"STD Recorder" indicates station consists of STD data or a mixture of STD and Nansen cast data.
TRACE DIR (B)	"Trace" indicator U (UP), D (DOWN), and A (AVERAGED)—used with STD casts, and specify that data were taken while hoisting or lowering respectively or that the two traces were averaged
DURATION (B)	Time elapsed during raising or lowering of the STD recorder to tenths of hours.
ORIG (R)	Originator's reference number in two parts—cruise number or 3 characters (if year of cruise forms part of cruise number years digits may sometimes only be found in "Year" field), and station number.
TEN SQ	Ten-degree square—modified Canadian square number.
5 SQUARE	Five-degree squares—modified Canadian system.
2 SQUARE	Two-degree squares—modified Canadian system.
1 SQUARE	One-degree squares—modified Canadian system.
CASTNUM (B)	Number of cast on multicast stations (blank when messenger time is given).
TIME (R)	Time of release of messenger in hour and tenths for applicable observed levels. If multicast series extends past midnight, 24 hours are added to cast time of next day. Beginning time for STD is given at first obs depth.
LVLTP	Type of record at depth indicated. "OBS"—observed values. For STD recorder = level of data read-out. "STD"—NODC standard interpolated values. "ORG"—Standard or other depths carrying non-NODC interpolated values. "LIT"—Interpolated standard depth values used as obs for computational purposes. Note—When an observed level coincides with a STD depth level, both "STD" and "OBS" lines will appear.
DEPTH	Depth of sample (or standard level) in whole meters. Prefix "T" indicates thermometrically determined depth (depth of unprotected thermometers). Subscript "Q" indicates that the value is marked doubtful by the originator. A value designated as plausible by NODC is marked with a "P". Postscript "Z" indicates uncorrected and inaccurate 'Wire-out' depths, (high wire angle present)
TEMP (B)	Temperature in degrees celsius. For 'Q' and 'P' notation see depth field
SAL (B)	Salinity in parts per thousand. For 'Q' and 'P' notation see depth field
SIGMA-T (B)	Seawater density anomaly to 2 decimal places. When depth, temp, or salinity is doubtful, a 'Q' is suffixed. An asterisk indicates a decrease of 0.02 or more from the previous level.
DYNPTH	Dynamic depth anomaly in dynamic meters to millimeters.
SND VEL (B)	Sound velocity in meters per second to decimeters according to Wilson's formula. (A standard depth-pressure term is used for stations not beginning at the surface)
OXYG (B)	Oxygen in ML/L to hundredths.
